

5 mounted on said doorframe such that said door may only be opened
 outwardly;

a locking arm mount being fixedly attached to the first side of the doorframe;
an arm having a first end and a second end, said first end being pivotally coupled
to said locking arm mount such that said arm is selectively positionable
10 between a first position extending away from the frame and a second
 position extending across the door, a loop being attached to said arm, said
 loop being positioned generally adjacent to said second end of said arm;

a lock mount being fixedly attached to the second side of the doorframe, said lock
mount being positioned such that said second end of said arm may abut
15 said lock mount when said arm is in said second position, said lock mount
 including a rod being attached to said second side, a cylinder having a
 perimeter wall attached to an end of said rod and being positioned adjacent
 to the door such that a plane of the door extends through said cylinder,
 said perimeter wall having a slot extending therethrough, said slot being
20 positioned for receiving said loop, said cylinder having an inner edge and
 an outer edge, said inner edge being positioned adjacent to the frame, a bar
 being mounted in said cylinder, said bar being positioned adjacent to said
 outer edge; and

wherein a lock may be positioned in said cylinder and positioned on said loop for
25 selectively locking said arm in said second position, wherein the lock is
 positioned between said bar and said inner edge of said cylinder.

2. (original) The locking assembly of claim 1, wherein said locking arm
mount includes a pair of plates being spaced from each other, each of said plates being in
30 a plane orientated substantially parallel to each other, said first end being positioned
 between and pivotally coupled to said plates.

3. (original) The locking assembly of claim 1, wherein said arm is
telescoping and includes a first portion being slidably positioned in a second portion.

5 Claims 4 and 5 (cancelled)

6. (currently amended) ~~A locking assembly for attaching to a doorframe for selectively locking a door in a closed position, the doorframe including a first side and a second side positioned opposite with respect to each other, the door being mounted on the frame such that door may only be opened outwardly, said locking assembly including:~~

A door locking assembly for selectively locking a door in a closed position, said assembly comprising:

a doorframe including a first side and a second side positioned opposite with respect to each other and facing laterally away from the door, a door being mounted on said doorframe such that said door may only be opened outwardly;

a locking arm mount being fixedly attached to the first side of the doorframe, said locking arm mount including a pair of plates being spaced from each other, each of said plates being in a plane orientated substantially parallel to each other;

an arm having a first end and a second end, said first end being pivotally coupled to said locking arm mount such that said arm is selectively positionable between a first position extending away from the frame and a second position extending across the door, said first end being positioned between and pivotally coupled to said plates, said arm being telescoping and including a first portion being slidably positioned in a second portion, a loop being attached to said arm, said loop being positioned generally adjacent to said second end of said arm;

a lock mount being fixedly attached to the second side of the doorframe, said lock mount being positioned such that said second end of said arm may abut said lock mount when said arm is in said second position, said lock mount including a rod being attached to said second side, a cylinder having a perimeter wall attached to an end of said rod and being positioned adjacent to the door such that a plane of the door extends through said cylinder, said perimeter wall having a slot extending therethrough, said slot being

5 positioned for receiving said loop, said cylinder having an inner edge and an outer edge, said inner edge being positioned adjacent to the frame, a bar being mounted in said cylinder, said bar being positioned adjacent to said outer edge; and

wherein a lock may be positioned in said cylinder and positioned on said loop for
10 selectively locking said arm in said second position, wherein the lock is positioned between said bar and said inner edge of said cylinder.

7. (new) A method of locking door providing the steps of:

providing a doorframe including a first side and a second side positioned opposite
15 with respect to each other and facing laterally away from the door, a door being mounted on said doorframe such that said door may only be opened outwardly;

providing a locking arm mount being fixedly attached to the first side of the doorframe, said locking arm mount including a pair of plates being spaced
20 from each other, each of said plates being in a plane orientated substantially parallel to each other;

providing an arm having a first end and a second end, said first end being pivotally coupled to said locking arm mount such that said arm is selectively positionable between a first position extending away from the
25 frame and a second position extending across the door, said first end being positioned between and pivotally coupled to said plates, said arm being telescoping and including a first portion being slidably positioned in a second portion, a loop being attached to said arm, said loop being positioned generally adjacent to said second end of said arm;

30 providing a lock mount being fixedly attached to the second side of the doorframe, said lock mount being positioned such that said second end of said arm may abut said lock mount when said arm is in said second position, said lock mount including a rod being attached to said second side, a cylinder having a perimeter wall attached to an end of said rod and
35 being positioned adjacent to the door such that a plane of the door extends

5 through said cylinder, said perimeter wall having a slot extending
therethrough, said slot being positioned for receiving said loop, said
cylinder having an inner edge and an outer edge, said inner edge being
positioned adjacent to the frame, a bar being mounted in said cylinder,
said bar being positioned adjacent to said outer edge; and
10 providing a padlock;
positioning said loop in said slot; and
locking said padlock on said slot such that said padlock is positioned between said
bar and said inner edge of said cylinder.
